## Chapter 5

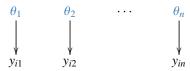

- 5.1 Lead-in to hierarchical models
- 5.2 Exchangeability (useful concept)
- 5.3 Bayesian analysis of hierarchical models (we use Stan/brms for computation)
- 5.4 Hierarchical normal model (we use Stan/brms for computation)
- 5.5 Example: parallel experiments in eight schools (useful discussion on benefits of hierarchical model)
- 5.6 Meta-analysis (can be skipped)
- 5.7 Weakly informative priors for hierarchical variance parameters

### Hierarchical model

- In simple model: posterior for the parameters
- In hierarchical model: posterior for the prior parameters

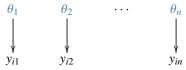

### Hierarchical model

- Example: CVD treatment effectiveness
  - in hospital j the survival probability is  $\theta_i$
  - observations  $y_{ij}$  tell whether patient i survived in hospital j

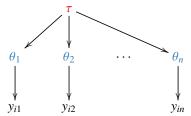

### Hierarchical model

- Example: CVD treatment effectiveness
  - in hospital j the survival probability is  $\theta_i$
  - observations  $y_{ij}$  tell whether patient i survived in hospital j

• sensible to assume that  $\theta_j$  are similar

- natural to think that  $\theta_i$  have common population distribution
- $\theta_j$  is not directly observed and the population distribution is unknown

## Hierarchical model: terms

Level 1: observations given parameters  $p(y_{ij} | \theta_j)$ 

$$p(\theta_j \mid \tau)$$
  $\theta_1$   $\theta_2$  ...  $\theta_n$  parameters  $p(y_{ij} \mid \theta_j)$   $y_{i1}$   $y_{i2}$   $y_{in}$  observations

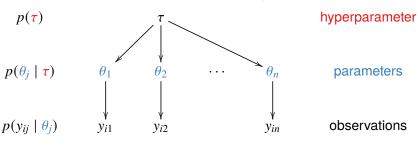

Joint posterior

$$p(\theta, \tau \mid y) \propto p(y \mid \theta, \tau)p(\theta, \tau)$$
$$\propto p(y \mid \theta)p(\theta \mid \tau)p(\tau)$$

## Hierarchical model: terms

Level 1: observations given parameters  $p(y_{ij} \mid \theta_j)$ 

Level 2: parameters given hyperparameters  $p(\theta_j \mid \tau)$ 

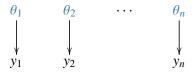

Joint posterior

$$\begin{array}{ccc} p(\theta,\tau\mid y) & \propto & p(y\mid \theta,\tau)p(\theta,\tau) \\ & \propto & p(y\mid \theta)p(\theta\mid \tau)p(\tau) \end{array}$$

 Hierarchical binomial model for rats prior parameters α and β are unknown

$$\theta_j \mid \alpha, \beta \sim \text{Beta}(\theta_j \mid \alpha, \beta)$$

$$y_j \mid n_j, \theta_j \sim \text{Bin}(y_j \mid n_j, \theta_j)$$

- Joint posterior  $p(\theta_1, \dots, \theta_J, \boldsymbol{\alpha}, \boldsymbol{\beta} \mid \boldsymbol{y})$ 
  - multiple parameters

 Hierarchical binomial model for rats prior parameters α and β are unknown

$$\theta_j \mid \boldsymbol{\alpha}, \boldsymbol{\beta} \sim \operatorname{Beta}(\theta_j \mid \boldsymbol{\alpha}, \boldsymbol{\beta})$$

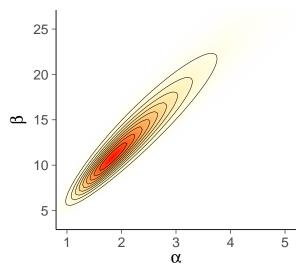

$$y_j \mid n_j, \theta_j \sim \text{Bin}(y_j \mid n_j, \theta_j)$$

- Joint posterior  $p(\theta_1, \dots, \theta_J, \alpha, \beta \mid y)$ 
  - multiple parameters
  - factorize  $\prod_{j=1}^{J} p(\theta_j \mid \alpha, \beta, y) p(\alpha, \beta \mid y)$

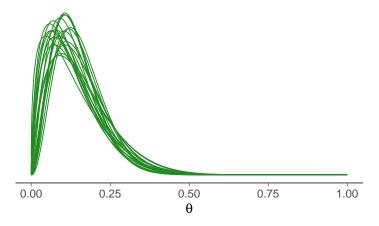

- Population prior Beta( $\theta_j \mid \alpha, \beta$ )
- Hyperprior  $p(\alpha, \beta)$ ?
  - $\alpha$ ,  $\beta$  both affect the location and scale
  - BDA3 has  $p(\alpha, \beta) \propto (\alpha + \beta)^{-5/2}$ 
    - diffuse prior for location and scale (BDA3 p. 110)
- demo5\_1

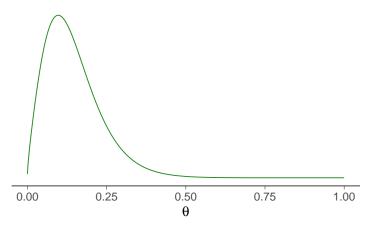

# The marginal of $\alpha$ and $\beta$

Beta( $\alpha, \beta$ ) given posterior draws of  $\alpha$  and  $\beta$ 

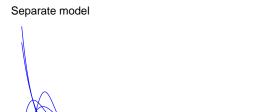

# Population distribution (prior) for $\boldsymbol{\theta}_j$

## Diet effect on chicken weights (at age 12 days)

- A typical treatment effect analysis
- Models
  - a separate model, in which each diet is modeled individually
  - a pooled model, in which all measurements are combined and there is no distinction between diets
  - a hierarchical model

diet\_idx is a vector with each element indicating the group

```
model {
  // Priors
  for (diet in 1:N_diets) {
    mu_diet[diet] ~ normal(mu_0, sd);
  mu_0 \sim normal(0, 1);
  sd \sim normal(0, 1)
  sigma \sim normal(0, 1);
  // Observation model
  for (obs in 1:N_observations) {
    weight[obs] ~ normal(mu_diet[diet_idx[obs]], sigma);
```

mu\_0 and sd are the population mean and sd

```
model {
  // Priors
  for (diet in 1:N_diets) {
    mu_diet[diet] ~ normal(mu_0, sd);
  mu_0 \sim normal(0, 1);
  sd \sim normal(0, 1)
  sigma \sim normal(0, 1);
  // Observation model
  for (obs in 1:N_observations) {
    weight[obs] ~ normal(mu_diet[diet_idx[obs]], sigma);
```

sd is constrained to be positive and thus the prior is half-normal

```
model {
  // Priors
  for (diet in 1:N_diets) {
    mu_diet[diet] ~ normal(mu_0, sd);
  mu_0 \sim normal(0, 1);
  sd \sim normal(0, 1)
  sigma \sim normal(0, 1);
  // Observation model
  for (obs in 1:N_observations) {
    weight[obs] ~ normal(mu_diet[diet_idx[obs]], sigma);
```

sigma is constrained to be positive and thus the prior is half-normal

```
model {
  // Priors
  for (diet in 1:N_diets) {
    mu_diet[diet] ~ normal(mu_0, sd);
  mu_0 \sim normal(0, 1);
  sd \sim normal(0, 1)
  sigma \sim normal(0, 1);
  // Observation model
  for (obs in 1:N_observations) {
    weight[obs] ~ normal(mu_diet[diet_idx[obs]], sigma);
```

## Stan without loops

#### Vectorized statements

```

| Intercept  | 2.36     | 0.37      | 1.60             | 3.10            | 1.00 | 860      | 1179     |
| assignment | -0.21    | 0.03      | -0.27            | -0.14           | 1.00 | 1073     | 1464     |

brms uses by default multivariate normal population prior for multiple varying coefficients, with LKJ prior on the correlation matrix

### Centered vs non-centered parameterization

HMC divergences are more likely when using hierarchical models

Hierarchical model code from the course demos

Hierarchical model code from the course demos

```
data {
                                    // number of observations
  int<lower=0> N:
  int<lower=0> K;
                                    // number of groups
  array[N] int<lower=1, upper=K> x; // discrete group indicators
  vector[N] y;
                                    // real valued observations
parameters {
  real mu0;
                                    // prior mean
  real<lower=0> sigma0;
                                    // prior std constrained to be pos.
  vector[K] mu;
                                    // group means
  real<lower=0> sigma;
                                  // common std constrained to be pos.
```

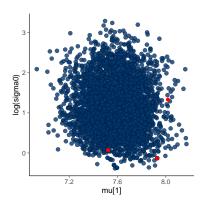

#### Hierarchical model code from the course demos

```
data {
                                   // number of observations
 int<lower=0> N:
 int<lower=0> K;
                                   // number of groups
 array[N] int<lower=1, upper=K> x; // discrete group indicators
 vector[N] y;
                                   // real valued observations
parameters {
 real mu0;
                                   // prior mean
 real<lower=0> sigma0;
                                   // prior std constrained to be pos.
 vector[K] mu;
                                   // group means
 real<lower=0> sigma;
                                 // common std constrained to be pos.
model {
 mu0 ~ normal(10, 10);
                                   // weakly informative prior
 sigma0 \sim normal(0, 10);
                                   // weakly informative prior
 mu ~ normal(mu0, sigma0);
                           // population prior with unknown param.
 sigma ~ lognormal(0, .5);
                           // weakly informative prior
 y ~ normal(mu[x], sigma);
                            // observation model
```

First data with many observations per group: 3 summer months with each having 71 observations.

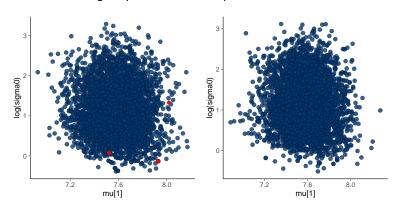

First data with many observations per group: 3 summer months with each having 71 observations.

A few divergences that are not clustered.

First data with many observations per group: 3 summer months with each having 71 observations.

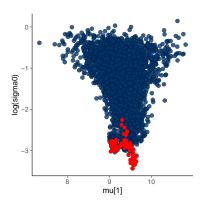

And decreasing step size a little helps.

Second data with a few observations per group: 71 years with each having 3 observations.

Second data with a few observations per group: 71 years with each having 3 observations.

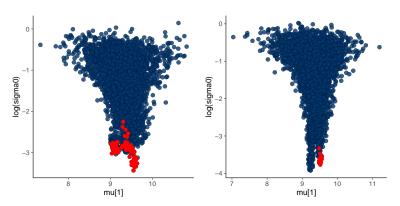

Many divergences that are clustered.

# Centered parameterization

Second data with a few observations per group: 71 years with each having 3 observations.

And decreasing step size doesn't remove the problem.

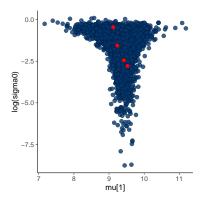

#### Transformation

```
parameters {
 real mu0;
                                   // prior mean
 real<lower=0> sigma0;
                                   // prior std constrained to be pos.
 vector[K] z;
                                   // latent variable
                                   // common std constrained to be pos.
 real<lower=0> sigma;
transformed parameters {
 vector[K] mu = mu0 + sigma0 * z; // group means
model {
 mu0 ~ normal(10, 10); // weakly informative prior
 sigma0 ~ normal(0, 10); // weakly informative prior
 z ~ normal(0, 1); // unit normal
 sigma ~ lognormal(0, .5); // weakly informative prior
 y ~ normal(mu[x], sigma); // observation model
```

Second data with a few observations per group: 71 years with each having 3 observations.

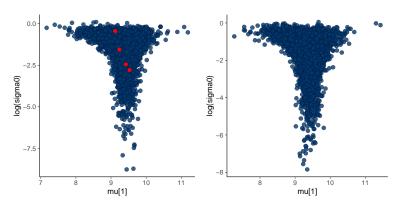

Second data with a few observations per group: 71 years with each having 3 observations.

A few divergences that are not clustered.

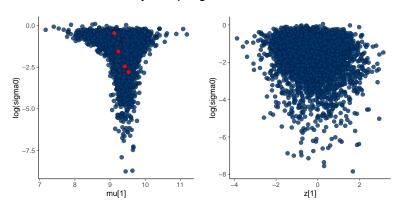

Second data with a few observations per group: 71 years with each having 3 observations.

And decreasing step size a little helps.

Second data with a few observations per group: 71 years with each having 3 observations.

Because we're actually sampling z and not mu

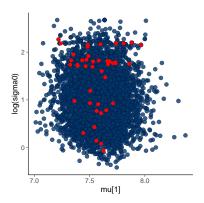

#### No free lunch

- non-centered parameterization is good when likelihood is weak
- non-centered parameterization is bad when likelihood is strong

First data with many observations per group: 3 summer months with each having 71 observations.

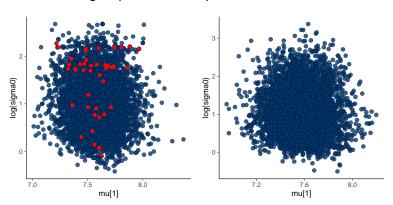

First data with many observations per group: 3 summer months with each having 71 observations.

Many divergences that are not clustered.

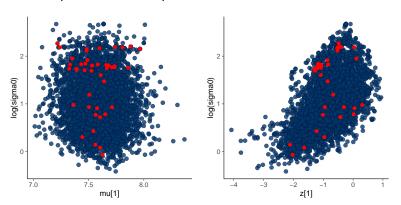

First data with many observations per group: 3 summer months with each having 71 observations.

But decreasing step size a lot helps.

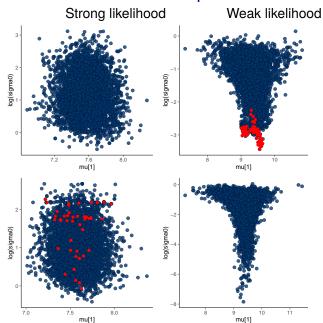

First data with many observations per group: 3 summer months with each having 71 observations.

Now the posterior for z is problematic.

## Centered vs. non-centered parameterization

#### brms and rstanarm

- brms and rstanarm use non-centered parameterization
  - as hierarchical models and Bayesian inference is most useful when likelihood is weak

#### brms and rstanarm

- brms and rstanarm use non-centered parameterization
  - as hierarchical models and Bayesian inference is most useful when likelihood is weak
- If the likelihood is highly informative for all groups, and the non-centered parameterization is causing divergences,
  - use non-hierarchical model as the hierarchical part is not that important with strong likelihood. Instead of

```
y ~ 1 + (1 | group)
use
y ~ 1 + group
```

#### brms and rstanarm

- brms and rstanarm use non-centered parameterization
  - as hierarchical models and Bayesian inference is most useful when likelihood is weak
- If the likelihood is highly informative for all groups, and the non-centered parameterization is causing divergences,
  - use non-hierarchical model as the hierarchical part is not that important with strong likelihood. Instead of

```
y ~ 1 + (1 | group)
use
y ~ 1 + group
```

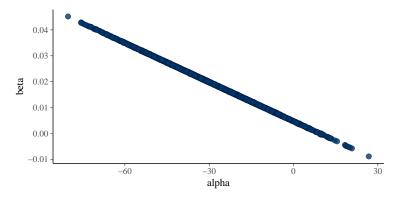

- There can be need for both centered and non-centered parameterization in the same model
  - automation not easy, but research goes on

# brms non-centered parameterization

```
parameters {
  real Intercept; // temporary intercept for centered predictors
  real<lower=0> sigma; // dispersion parameter
  vector<lower=0>[M_1] sd_1; // group-level standard deviations
  array[M_1] vector[N_1] z_1; // standardized group-level effects
transformed parameters {
 vector[N_1] r_1_1; // actual group-level effects
 r_1_1 = (sd_1[1] * (z_1[1]));
//...
model {
//...
    for (n in 1:N) {
     // add more terms to the linear predictor
     mu[n] += r_1_1[J_1[n]] * Z_1_1[n];
//...
 target += std_normal_lpdf(z_1[1]);
```

# Kilpisjärvi summer temperature

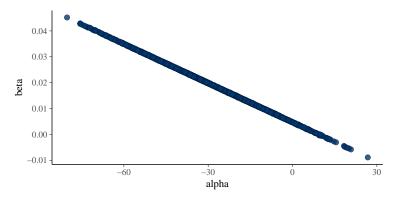

#### Posterior draws of alpha and beta

Warning: 1 of 4000 (0.0%) transitions hit the maximum treedepth limit of 10. See https://mc-stan.org/misc/warnings for details.

# Kilpisjärvi summer temperature

#### Posterior draws of alpha and beta

Warning: 1 of 4000 (0.0%) transitions hit the maximum treedepth limit of 10. See https://mc-stan.org/misc/warnings for details.

Solution was to center the covariate time to have mean 0, so that the intercept is the expected temperature in the middle of the range

# brms covariate centering by default

```
fit_lin <- brm(temp ~ year, data = data_lin)</pre>
```

# brms covariate centering by default

```
fit_lin <- brm(temp ~ year, data = data_lin)</pre>
transformed data {
 matrix[N. Kc] Xc: // centered version of X without an intercept
  vector[Kc] means_X; // column means of X before centering
  for (i in 2:K) {
   means_X[i - 1] = mean(X[, i]);
   Xc[, i - 1] = X[, i] - means_X[i - 1];
parameters {
  vector[Kc] b: // regression coefficients
  real Intercept; // temporary intercept for centered predictors
  real<lower=0> sigma: // dispersion parameter
model {
//...
 target += normal_id_glm_lpdf(Y | Xc, Intercept, b, sigma);
//...
generated quantities {
 // actual population-level intercept
  real b_Intercept = Intercept - dot_product(means_X, b);
```

## brms covariate centering by default

Sometimes we want to turn off the covariate centering, which can be done with additional argument for brms formula function bf()

```
fit_lin <- brm( bf(temp ~ year, center=FALSE) , data = data_lin)</pre>
```

| model                      | formula | alternative formula |

### brms families

family argument determines the observation model family

| model   | brms  |
|---|---|
| $y \sim t_{\nu}(\alpha + \beta x, \sigma)$                  | y ~ x, family = student()                         |
| $y \sim \text{Bin}(\text{logit}^{-1}(\alpha + \beta x), N)$ | <pre>y   trials(N) ~ x, family = binomial()</pre> |
| $y \sim \text{Neg-bin}(\exp(\alpha + \beta x), \phi)$       | y ~ x, family = negbinomial()                     |

### BDA course demo for brms

Link in the course web site or directly

 $https://avehtari.github.io/BDA\_R\_demos/demos\_rstan/brms\_demo.html$ 

- Justifies why we can use
  - a joint model for data
  - a joint prior for a set of parameters
- Less strict than independence

- Exchangeability: Parameters  $\theta_1, \ldots, \theta_J$  (or observations  $y_1, \ldots, y_J$ ) are exchangeable if the joint distribution p is invariant to the permutation of indices  $(1, \ldots, J)$
- e.g.

$$p(\theta_1, \theta_2, \theta_3) = p(\theta_2, \theta_3, \theta_1)$$

• Exchangeability implies symmetry: If there is no information which can be used *a priori* to separate  $\theta_j$  form each other, we can assume exchangeability. ("Ignorance implies exchangeability")

- Exchangeability does not mean that the results of the experiments could not be different
  - e.g. if we know that the experiments have been in two different laboratories, and we know that the other laboratory has better conditions for the rats, but we do not know which experiments have been made in which laboratory
  - a priori experiments are exchangeable
  - model could have unknown parameter for the laboratory with a conditional prior for rats assumed to come form the same place (clustering model)

# Exchangeability and additional information

- Example: bioassay
  - $y_i$  number of dead animals are not exchangeable alone

# Exchangeability and additional information

- Example: bioassay
  - y<sub>i</sub> number of dead animals are not exchangeable alone
  - $x_i$  dose is additional information

## Exchangeability and additional information

- Example: bioassay
  - y<sub>i</sub> number of dead animals are not exchangeable alone
  - x<sub>i</sub> dose is additional information
  - $(x_i, y_i)$  exchangeable and logistic regression was used

$$p(\alpha, \beta \mid y, n, x) \propto \prod_{i=1}^{n} p(y_i \mid \alpha, \beta, n_i, x_i) p(\alpha, \beta)$$

- Example: hierarchical rats example
  - all rats not exchangeable

- Example: hierarchical rats example
  - all rats not exchangeable
  - in a single laboratory rats exchangeable

- Example: hierarchical rats example
  - all rats not exchangeable
  - in a single laboratory rats exchangeable
  - laboratories exchangeable

- Example: hierarchical rats example
  - all rats not exchangeable
  - in a single laboratory rats exchangeable
  - laboratories exchangeable
  - → hierarchical model

# Partial or conditional exchangeability

- Conditional exchangeability
  - if y<sub>i</sub> is connected to an additional information x<sub>i</sub>, so that y<sub>i</sub> are not exchangeable, but (y<sub>i</sub>, x<sub>i</sub>) exchangeable use joint model or conditional model (y<sub>i</sub> | x<sub>i</sub>).

## Partial or conditional exchangeability

- Conditional exchangeability
  - if y<sub>i</sub> is connected to an additional information x<sub>i</sub>, so that y<sub>i</sub> are not exchangeable, but (y<sub>i</sub>, x<sub>i</sub>) exchangeable use joint model or conditional model (y<sub>i</sub> | x<sub>i</sub>).
- Partial exchangeability
  - if the observations can be grouped (a priori), then use hierarchical model

• The simplest form of the exchangeability (but not the only one) for the parameters  $\theta$  conditional independence

$$p(x_1,\ldots,x_J\mid\theta)=\prod_{j=1}^J p(x_j\mid\theta)$$

## Exchangeability - Counter example

- A six sided die with probabilities  $\theta_1, \ldots, \theta_6$ 
  - without additional knowledge  $\theta_1, \ldots, \theta_6$  exchangeable
  - due to the constraint  $\sum_{j=1}^6 \theta_j$ , parameters are not independent and thus joint distribution can not be presented as iid

See more examples in the BDA3 notes - Exchangeability vs. independence
